c High Business Technical School, Doboj, Bosnia and Herzegovina

In this paper we have looked into the qualitative analysis of coals in Bosnia and Herzegovina. The analysis includes the following characteristics: moisture, ash, combustible matter and lower heating value. From the statistic parameters we have determined: absolute range, arithmetic mean, standard deviation and variations coefficient. It has been shown that the coal characteristics have normal distribution. The analysis show that there are considerable deviations of ash characteristics: moisture (36.23%), ash (34.21%), combustible matter (16.15%), and lower heating value (25.16%) from the mean value which is shown by the variations coefficient. Large oscillations of mass portions: W, A, Vg, and Hd around the mean value can adversely influence the function of a boiler plant and an electric filter plant in thermal power plants in Bosnia and Herzegovina in which the mentioned types of coal burn. Large ash oscillations (34.21%) around the mean value point out to the inability of application of dry procedures of desulphurisation of smoke gasses due to the additional quantity of ash. It has been shown that the characteristics of Bosnian types of coal do not deviate a lot from the characteristics of coal in the surrounding countries (coals of Serbia and Montenegro). The results can be used in analysis of coal combustion in thermal power plants, optimisation of electrical-filtre, reduction of SO2 in smoke gas, and other practical problems.

Key words: coal, thermal power plant, qualitative analysis

Introduction

Installed power in the four thermal power plants in Bosnia and Herzegovina (B&H) for the production of electricity is 1957 MW with the production of about 8300 GWh or 60.6% of total produced electricity (tab. 1). From tab. 1 can be seen that the blocks installed in (B&H) have been used mainly between 25 and 30 years, some over 40 years. In normal circumstances, for these blocks, a question of replacement can be raised. The basic criteria for such decision, apart from the price of capital, are the prognosis of market situation of electricity (placement and price), prognosis of production expenses (energetic efficiency of a plant and the price of fuel), as
well as meeting the conditions of the minimal effect of the plant to the environment [1, 2]. Industrial testings of electric filter plants in the observed thermal power plants show large emissions of sulphur oxides and emission of ash into the atmosphere [3].

Coals that combust in the boiler plants of thermal power plants in B&H are bad quality (large quantity of sulphur, moisture, and ash) (fig. 1 and tab. 2).

Figure 1. Map of mines and thermal power plants in B&H
In the revitalisation process, thermal powerplants in B&H will have to adjust to the new quality of coals which is in reality very often a mixture (homogenisation) of coals [5, 6]. In that aspect the aim of this article is the qualitative analysis of coals combusted in boilers of thermal power plants in B&H. Analysis should determine the quality of used coals and the possibility of application of obtained results in practice (coal homogenisation, electric filter optimisation, reduction of SO₂ in smoke gasses, designing devices for desulphurisation of smoke gasses (FGD), etc.). In the qualitative analysis of coals in B&H, the following characteristics are included: moisture, ash, combustible matter, and lower heating value.

Qualitative rating of coal characteristics in B&H

Of the statistic parameters we have determined [9-11]:

(1) absolute range \( R = \max. X_i - \min. X_i, (i = 1, 2, 3, \ldots, n) \) (1)

(2) arithmetic mean \( \bar{X} = \frac{1}{n} \sum_{i=1}^{n} X_i, \) or \( \bar{X} = \frac{1}{n} \sum_{i=1}^{n} f_i X_i \) (2)

(3) standard deviation \( S = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} (X_i - \bar{X})^2}, \) or \( S = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} f_i (X_i^* - \bar{X})^2} \) (3)

(4) variation coefficient \( C_V = \frac{S}{\bar{X}} \times 100 \) (4)
where \( n \) is the number of elements of sample characteristics, \( X_i \) – the value of considered coal characteristics, and \( X_i^* \) – the mean interval of coal characteristics.

Pearson’s \( \chi^2 \) criterium will check whether the coal samples are in concordance with the assumption that a random variable (coal characteristics) \( X \) has the function of distribution \( F(x) \) (normal distribution), or the deviations are large so the assumption has to be discarded. When determining the value of Pearson’s \( \chi^2 \) criterium, the following is used:

\[
k = 1 + 3.3\log n
\]  
(5)

\[
i = \frac{R}{k}
\]  
(6)

\[
u_i = \frac{X_i - \bar{X}}{S}
\]  
(7)

\[
\Phi(u_i) = \frac{1}{\sqrt{2\pi}} \int_0^{\frac{u_i}{\sigma}} e^{-t^2/2} dt
\]  
(8)

\[
p_i = P(X_{i-1} < X < X_i) = \Phi(u_i) - \Phi(u_{i-1})
\]  
(9)

where \( k \) is the number of intervals, \( i \) – the size of an interval, \( p_i \) – the probability that the random variable \( X \in N(\mu, \sigma) \) takes the value in the interval \([X_{i-1}, X_i]\), \( P \) – the probability, \( \mu \) – the mean value of statistic population, \( \sigma \) – the standard deviation of statistic population, \( u_i \) – the replacement (alternation) of variables, and \( \Phi(u_i) \) – the Laplas function.

Testing of the mean values of coal characteristics has been carried out by using Student’s \( t \) test at the level of significance (risk) \( \alpha = 0.05 \) and the following expressions have been used:

\[
l = n - 1
\]  
(10)

\[
[\bar{X} - \frac{t_{n-1,\alpha}}{\sqrt{n-1}} S; \bar{X} + \frac{t_{n-1,\alpha}}{\sqrt{n-1}} S]
\]  
(11)

where \( l \) is the number of degrees of freedom, \( t_{n-1,\alpha} \) – the variable which is determined from the table for Student’s distribution at the selected level of significance (trust) \( \alpha \), and for the degree of freedom \( l = n - 1 \).

By using numerical values of coal characteristics from tab. 2 and the expressions from (1) to (4) the calculation of some parameters for coal characteristic „moisture” is:

\[
R = \max X - \min X = 50.00 - 15.10 = 34.90\%
\]

\[
\bar{X} = \frac{1}{n} \sum_{i=1}^{n} X_i = \frac{35.00 + 32.20 + \ldots + 15.10 + 21.93}{9} = 30.69\%
\]

\[
S = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} (X_i - \bar{X})^2} = \sqrt{\frac{(X_1 - \bar{X})^2 + (X_2 - \bar{X})^2 + \ldots + (X_9 - \bar{X})^2}{9 - 1}} = \sqrt{\frac{(35.00 - 30.69)^2 + (32.20 - 30.69)^2 + \ldots + (15.10 - 30.69)^2 + (21.93 - 30.69)^2}{8}} = 11.12
\]

\[
C_v = \frac{S}{\bar{X}} \times 100 = 36.23\%
\]
In tab. 3 the statistical results of calculation for the coals of B&H are shown. Variations coefficient ($C_v$) points out to deviations of the observed coal characteristics from the mean value. The largest deviation from the mean value refers to the coal characteristic moisture ($W$) and it is 36.23 % and ash ($A$) of 34.21%. This points out to larger oscillations of mass contents of ash and moisture in coals of B&H which can adversely influence the function of a boiler plant and an electric filter plant in thermal power plant objects such as power plants.

### Table 3. Qualitative characteristics of Bosnian coals

<table>
<thead>
<tr>
<th>Coal characteristics</th>
<th>Statistic parameters</th>
</tr>
</thead>
<tbody>

<td>$V_g$, [%]</td>
<td>25.08</td>
</tr>
<tr>
<td>$H_d$, [kJkg$^{-1}$]</td>
<td>9369.00</td>
</tr>
</tbody>
</table>

According to expressions (5) to (11) for the feature (characteristic) of coal „moisture“ the calculation of certain parameters is:

$$k = 1 + 3.3 \log n = 1 + 3.3 \log 9 = 4.15 \approx 4$$

$$i = \frac{R}{k} = \frac{3490}{4} = 873$$

The lowest value of standardised variable $u_i = (X_i - \bar{X})/S = (15.10 - 30.69)/11.12 = -1.40$ has been replaced with $-\infty$, and the largest value of standardised variable $u_i = (X_i - \bar{X})/S = (50.00 - 30.69)/11.12 = 1.74$ with $+\infty$ since the random variable $X \in N(\mu, \sigma)$ has been defined in the interval $(-\infty, +\infty)$. All the calculations have been arranged and shown in tab. 4.

<td>9</td>
<td></td>
<td></td>
<td>1.0000</td>
<td>9</td>
<td></td>
<td>$\chi^2_2 = 0.6938$</td>
</tr>
</tbody>
</table>

The result we got is $\chi^2_2 = 0.6938$. From the tables for the level of significance $\alpha = 0.05$ and number of degrees of freedom $r = k - r - 1 = 4 - 2 - 1 = 1 (r = 2$, number of unknown parame-
ters \( \mu \) and \( \sigma \), the critical value \( \chi^2_{kr} = \chi^2_{0.05,1} = 3.84 \) can be found. Since \( \chi^2 > \chi^2_{kr} \) the assumption on normal distribution of coal characteristic „moisture” can be adopted. In a similar way it can be shown that other coal characteristics \((A, V_g, H_d)\) are liable to normal distribution law. Now, we are going to determine the interval within which the real value of coal characteristic „wetness” with the probability of 95% moves.

For the number of degrees of freedom \( l = n - 1 \) and the level of significance \( \alpha = 0.05 \) and from the Student’s table of distribution it can be seen that \( t_{n-1,\alpha} = t_{8,0.05} = 2.31 \) i.e. according to the expression (11):

\[
30.69 - \frac{231}{\sqrt{8}} < \mu < 30.69 + \frac{231}{\sqrt{8}}
\]

or

\[
21.61% < \mu < 39.77%
\]

For other coal characteristics \((A, V_g, H_d)\) the intervals of reliability are shown in tab. 5.

If the mean values of coal characteristics belong to the calculated intervals (tab. 5) then, possible differences \( |X - \mu|\) can be assigned accidental, otherwise they are significant.

</table>

For the purpose of comparing coal characteristics of Bosnian coals to the surrounding coals (Serbia and Montenegro [7, 12]) on fig. 2 to 5 we have shown the dependence of lower heating value of coal, carbon, volatile components and fixed carbon reduced to combustible mass (basis without moisture and ash). It can be seen that coal characteristics in B&H do not deviate a lot from coal characteristics used in furnaces of boiler plants in Serbia and Montenegro, hence, the results can be applied not only on thermal power plants in B&H, but also on the thermal power plants in the surrounding area (Serbia and Montenegro).
Conclusions

By qualitative analysis of characteristics of Bosnian coals it has been shown that it is possible to accept the assumption that the considered coal characteristics (\( W, A, V_g, H_d \)) have normal distribution. If the mean values of coal characteristics belong to the calculated intervals (tab. 5) then, possible differences \( \frac{X - \mu}{c_{45}} \) can be assumed to be accidental, otherwise they are significant. The analysis shows that there are significant deviations of considered characteristics: moisture 36.23%, ash 34.21%, combustible matter 16.15%, and lower heating value 25.16% from mean values, which is shown by the variations coefficient \( C_v \) (tab. 3). Large oscillations of mass parts of considered coal characteristics around the mean value can adversely influence the function of a boiler plant and an electric filter plant in thermal power plants in B&H. This also points out to inability of application of dry procedures of FGD due to the additional quantity of ash. Unsteadiness of coals quality used in thermal power plants in B-H indicates the need of equalization (homogenisation) of coals quality. Using a blended (homogenised) coal would cause a wide range of positive effects like: increasing a heating value, lowering a moisture, and ash in coal which results in better combusting and more stability in thermal power plant production. This is in concordance with the result of measuring and testing electric filter plants in thermal power plants in B&H and the need for reconstruction of existing and building new thermal blocks for coal.

As B&H coal characteristics do not deviate a lot from other coals in the surrounding countries (coals of Serbia and Montenegro) (fig. 2-5), the results can be applied to thermal power plants in Serbia and Montenegro in which lignite burns. This conclusion is in concordance with the testing results and practical measuring.
