THE MOTION OF A NON-NEWTONIAN NANOFUID OVER
A SEMI-INFINITE MOVING VERTICAL PLATE THROUGH
POROUS MEDIUM WITH HEAT AND MASS TRANSFER

The motion of a non-Newtonian nanofuid over a semi-infinite moving vertical plate through porous medium stressed by an external uniform magnetic field with heat and mass transfer is investigated. The fluid under consideration obeys Eyring-Powell model. The effects of the physical parameters of the problem such as, permeability, chemical reaction as well as the fluid material parameters such as Hartmann number, Eckert number and Reynolds number are discussed. The effects of external cooling (Gr > 0) of the plate by the free convection are considered. Graphical results are presented to highlight effects of various emerging parameters on velocity, temperature and concentration profiles.

Key words: Boundary layer; Eyring-Powel model; Nanofuids; Moving surface; Magnetic field; Porous media, Heat and mass transfer, chemical reaction, Vertical plate.

1- Introduction

At the beginning of the nineteenth century, Maxwell introduced the basic concepts of dispersing solid particles in fluids to enhance its thermal conductivity. Maxwell was one of the first to analytically investigate conduction through suspended particles [1]. By the end of the nineteenth century nanotechnology is widely used in engineering industries. In petroleum engineering industries, for example, when oil and gas companies turn their attention to new search areas. Nanotechnology can improve viscosity, density, specific gravity and any other physical properties of the drilling fluid to overcome any difficulties. Throughout any industrial facility, heat is added, removed, or moved from one process stream to another. These processes provide a source for energy recovery and fluid heating/cooling. Because of the rising development in modern technology, there is a need to develop new types of fluids that will be more effective in terms of heat exchange performance. Convectional heat transfer fluids, including oil, water, and ethylene glycol mixtures are poor heat transfer fluids, while the thermal conductivity of these fluids plays an important role in the heat transfer coefficient between the heat transfer medium and the heat transfer surface [2]. The thermal conductivity of fluids can be enhanced by adding nanoparticles to the base fluids ([3]–[9]).
In the last few decades many scientists and engineers studied the boundary layer flow over semi-infinite porous plates [10-17] with concentration on the fluid chemical reactions with heat and mass transfer under the influence of uniform magnetic field. Rashidi et al. [18] investigated heat the transfer of a steady incompressible water based nanofluid flow over a stretching sheet in the presence of transverse magnetic field with thermal radiation and buoyancy effects. Gupta et al. [19] studied the free convection of flow past a linearly accelerated vertical plate in the presence of viscous dissipative heat using perturbation method. Kafousias and Raptis [20] extended this problem to include mass transfer effects subjected to variable suction or injection. Raptis et al. [21] studied the free convection effects on flow past an accelerated vertical plate with variable suction and uniform heat flux in the presence of magnetic field. Soundalgekar et al. [22] analyzed the problem of free convection effects on Stokes problem for a vertical plate under the action of transversely applied magnetic field. The problem of steady laminar magneto hydrodynamic(MHD) mixed convection heat transfer about a vertical plate is solved numerically by Orhan Aydin and Ahmet Kaya [23] taking into account the effect of Ohmic heating and viscous dissipation. Tripathy et al. [24] considered chemical reaction impacts on free convection MHD fluid flow past a moving vertical permeable plate. In [25] Turkyilmazoglu studied Soret and Dufour effect on MHD flow with heat and mass transfer of an electrically conducting viscoelastic fluid past a vertical stretching surface in porous media.

Although different kinds of fluids are discussed by many researchers, other important fluids, such as thixotropic fluids, still needs more study. Thixotropic fluid is a fluid which takes a finite time to attain equilibrium viscosity when introduced to a steep change in shear rate. In 1944 Eyring and Powell [26] introduced a mathematical model, known as Eyring-Powell model, explaining the behavior of these fluids. This mathematical model is used by many researchers. Hayat et al. [27] considered heat analysis of Eyring-Powell fluid flow over a continuously moving surface with convective endpoint conditions. Reddy [28] studied the flow and heat transfer of Eyring Powell fluid over a continuously moving surface in the presence of a free stream velocity. Fluids satisfying Eyring-Powell model are studied by many researchers. [29-31]

In this paper we focus on studying the boundary layer flow of a non-Newtonian nanofluid, byes Eyring-Powell model, over a semi-infinite moving vertical plate in the presence of external uniform magnetic. Using appropriate transformation the governing system of partial differential equations of the problem is transformed to a system of ordinary differential equations. The Mathematica Parametric NDSolve package is employed to obtain the results numerically. Moreover the effect of the variation of the permeability, chemical reaction, Hartmann number and Eckert number on velocity distribution, temperature distribution and concentration are obtained and presented in figures.

2. Formulation of the problem

Consider two-dimensional steady boundary-layer flow of an incompressible nanofluid over a moving semi-infinite vertical flat plate. Chose the Cartesian coordinate system such that the x-axis is
taken along the continuous surface direction and the y-axis is normal to it (as shown in Figure 1). Let the fluid be influenced by uniform magnetic field $\vec{B} = (0, B_x, 0)$ normal to the moving surface.

\[
\begin{align*}
\text{Figure(1): Physical model and coordinate system}
\end{align*}
\]

Let $U$ being the velocity of the uniform free stream, $U_w = \lambda U$ being the flat plate velocity, where $\lambda$ is the plate velocity parameter. Assume that $T_w$ and $C_w$ are the values of the moving surface temperature and concentration respectively while in the ambient fluid these values are $T_\infty$ and $C_\infty$.

In Eyring-Powell model the stress tensor is written as [26]:

\[
\tau_{ij} = \mu \left( \frac{\partial v_i}{\partial x_j} + \frac{1}{\beta_f} \sinh^{-1} \left( \frac{1}{c} \frac{\partial v_i}{\partial x_j} \right) \right) - \sinh^{-1} \left( \frac{1}{c} \frac{\partial v_i}{\partial x_j} \right); \quad \frac{1}{c} \frac{\partial v_i}{\partial x_j} - \frac{1}{6} \left( \frac{1}{c} \frac{\partial v_i}{\partial x_j} \right)^3 , \quad \left| \frac{1}{c} \frac{\partial v_i}{\partial x_j} \right| \ll 1.
\]

where, $\mu$ is the dynamic viscosity, $\beta_f$ and $c$ are the characteristics of the Eyring-Powell model.

Taking in consideration the steady-state flow of the boundary layer, the governing equations of the considered problem are:

\[
\begin{align*}
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} &= 0 \\
\frac{u}{c} \frac{\partial u}{\partial x} + v \left( \frac{\partial u}{\partial y} \right) &= (\nu + \frac{1}{\beta_f c \rho_f}) \frac{\partial^2 u}{\partial y^2} - \frac{1}{\rho_f} (\sigma B_x^2 + \frac{\mu}{k}) u - \\
&- \frac{1}{2 \beta_f c \rho_f} \left( \frac{\partial u}{\partial y} \right)^2 \frac{\partial^2 u}{\partial y^2} + g \beta (T - T_\infty) + g \beta' (C - C_\infty) \\
\frac{u}{c} \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} &= \alpha \frac{\partial^2 T}{\partial y^2} + \tau [D_T \frac{\partial C}{\partial y} \frac{\partial T}{\partial y} + D_V \frac{\partial (\bar{T} + T)}{\partial y}] + \\
&+ \frac{\tau}{c} \left( \frac{\partial T}{\partial y} \right)^2. 
\end{align*}
\]
\[ \left( \frac{\mu}{(\rho c)_f} + \frac{1}{c_\beta (\rho c)_f} \right) \left( \frac{\partial u}{\partial y} \right)^2 + \frac{\sigma}{(\rho c)_f} B_\alpha^2 u^2 - \frac{1}{6c^3 \beta (\rho c)_f} \left( \frac{\partial u}{\partial y} \right)^4 \right) \]

\[ u \frac{\partial C}{\partial x} + v \frac{\partial C}{\partial y} = D_B \frac{\partial^2 C}{\partial y^2} + \frac{D_T}{T_e} \left( \frac{\partial^2 T}{\partial y^2} \right) + k_s (C - C_\infty), \]

The boundary conditions of the problem are:

\[ v = 0, \quad u = U_w = \lambda U, \quad T = T_w, \quad C = C_w \text{ at } y = 0, \]
\[ u \to U, \quad T \to T_\infty, \quad C \to C_\infty \text{ at } y \to \infty. \]

where \( u \) and \( v \) are the velocity components along the \( x \) and \( y \) axis respectively, \( v \) is the kinematic viscosity coefficient, \( \alpha \) is the fluid thermal diffusivity \( \alpha = k_c / (\rho c)_f \) and \( \tau = (\rho c)_f / (\rho c)_f \)

where \( k, k \), \( k_s \), and \( \sigma \) are the fluid thermal conductivity, permeability coefficient, the chemical reaction and fluid electric conductivity, \( \rho_f \), \( \rho_c \), and \( \rho_p \) are fluid density, fluid heat capacity and nanoparticles effective heat capacity, \( D_B \) and \( D_T \) are Brownian and thermophoretic diffusion coefficients.

Introducing the stream function \( \psi \) defined as \( u = \partial \psi / \partial y \) and \( v = -\partial \psi / \partial x \), which identically satisfies the continuity equation (3), we can write equations (4)-(6) as:

\[ \frac{\partial \psi}{\partial y} \frac{\partial^2 \psi}{\partial x \partial y} - \frac{\partial \psi}{\partial x} \frac{\partial^2 \psi}{\partial x^2} = \left( \frac{\nu}{c_\beta \rho_f} \right) \frac{\partial^3 \psi}{\partial y^3} - \frac{1}{\rho_f} \left( \frac{\sigma B_\alpha^2 + \mu}{k} \right) \frac{\partial \psi}{\partial y} - \frac{1}{2c^3 \beta \rho_f} \left( \frac{\partial^2 \psi}{\partial y^2} \right)^2 \frac{\partial^3 \psi}{\partial y^3} + g\beta \left( T - T_\infty \right) + g\beta' \left( C - C_\infty \right) \]

\[ \frac{\partial \psi}{\partial y} \frac{\partial T}{\partial x} - \frac{\partial \psi}{\partial x} \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2} + \tau \left[ D_B \frac{\partial C}{\partial y} \frac{\partial T}{\partial y} + \frac{D_T}{T_e} \left( \frac{\partial^2 T}{\partial y^2} \right) \right] + \]

\[ \left( \frac{\mu}{c_\beta (\rho c)_f} \right) \left( \frac{\partial^2 \psi}{\partial y^2} \right)^2 + \frac{\sigma}{(\rho c)_f} B_\alpha^2 \left( \frac{\partial \psi}{\partial y} \right)^2 - \frac{1}{6c^3 \beta (\rho c)_f} \left( \frac{\partial^2 \psi}{\partial y^2} \right)^4 \]

\[ \frac{\partial \psi}{\partial y} \frac{\partial C}{\partial x} + \frac{\partial \psi}{\partial x} \frac{\partial C}{\partial y} = D_B \frac{\partial^2 C}{\partial y^2} + \frac{D_T}{T_e} \left( \frac{\partial^2 T}{\partial y^2} \right) + k_s (C - C_\infty) \]

By introducing the similarity variable \( \eta = y (U / 2\nu x)^{1/2} \) and the stream function \( \psi = (2U\nu x)^{1/2} f(\eta) \) together with \( \theta(\eta) = (T(\eta) - T_\infty) / (T_w - T_\infty) \) and \( \varphi(\eta) = (C(\eta) - C_\infty) / (C_w - C_\infty) \), the system of equations (8)-(10) reduces to the following system of nonlinear ordinary differential equations:
\((1+\varepsilon)f''(\eta) + f(\eta)f''(\eta) - \left(M + \frac{1}{k}\right)f'(\eta) - \varepsilon\delta f^{*2}(\eta)f''(\eta) + 2R_{ex}(G, \theta + G, \phi) = 0,\)  
(11)

\[
\frac{1}{\rho} \varphi''(\eta) + f(\eta)\varphi'(\eta) + N_b \varphi'(\eta) + N_b \varphi'^2(\eta) + E(1+\varepsilon) f^{*2}(\eta) + 
\]

\[
M E_c f^{*2}(\eta) - \varepsilon\delta E_c f^{*4}(\eta) = 0
\]
(12)

\[
\varphi'(\eta) + \frac{N_b}{N_b} \varphi'(\eta) + L_c \varphi(\eta) + 2\gamma R_{ex}L_c \varphi(\eta) = 0,
\]
(13)

Subject to the boundary conditions:

\[f(0) = 0, \quad f'(0) = \lambda, \quad \varphi(0) = 1, \quad \text{as} \quad \eta \rightarrow 0,\]

and \(f'(\eta) \rightarrow 1, \quad \theta(\eta) \rightarrow 0, \quad \varphi(\eta) \rightarrow 0, \quad \text{as} \quad \eta \rightarrow \infty\)
(14)

Where,

\[
M = \frac{2\sigma B^2}{\nu}, \quad K = \frac{2\sigma \mu}{\nu k}, \quad E_i = \frac{U^2}{(C_f)_j(T_u - T_w)}, \quad L_c = \frac{\nu}{D_a}, \quad R_{ex} = \frac{U}{v}.
\]

\[\gamma = \frac{vk}{U^2}, \quad P_c = \frac{v}{\alpha}, \quad N_b = \frac{(\rho C_p)\beta D_a(C_u - C_w)}{(\rho c)_j v}, \quad N_i = \frac{(\rho C_p)\beta D_t(T_u - T_w)}{v(\rho c)_j T_u}
\]

\[
\varepsilon = \frac{1}{\mu \beta c}, \quad \delta = \frac{U^3}{2\nu \chi^2}, \quad G_r = \frac{g \beta u}{U^3} (T - T_u), \quad G_c = \frac{g \beta u}{U^3} (C - C_u)
\]
(15)

where \(M, K, E_i, L_c, \gamma, P_c, N_b, G_r, G_c\) and \(N_i\) are Hartmann number, permeability parameter, Eckert number, Lewis number, Reynolds number, chemical reaction parameter, Prandtl number, Brownian motion parameter, Grashof number, modified Grashof number and thermophoresis parameter. \(\varepsilon, \delta\) are the fluid material parameters. Moreover the problem physical quantities \(c_f, Nu_x\) and \(Sh_x\) (skin-friction coefficient, local Nusselt number and Local Sherwood number) are defined as:

\[
c_f = \frac{\tau_u}{\rho U^2}, \quad Nu_x = \frac{xq_u}{k(T_u - T_w)}, \quad Sh_x = \frac{xq_m}{D_a(C_u - C_w)}; \quad \tau_u = \left(\mu + \frac{1}{\beta c} \frac{\partial u}{\partial y} - \frac{1}{6\beta} \left(\frac{\partial u}{\partial y}\right)^3\right)
\]

\[
q_m = -\kappa \left(\frac{\partial T}{\partial y}\right)_{y=0}, \quad q_m = -D_a \left(\frac{\partial T}{\partial y}\right)_{y=0}
\]
(16)

Also, with the help of the similarity transformations we can write:

\[
\sqrt{2R_{ex}} C_f = (1+\varepsilon)f''(0) - \varepsilon\delta f^{*2}(0), \quad \theta'(0) = -\sqrt{2 \frac{R_{ex}}{Nu_x}}, \quad \varphi'(0) = -\sqrt{2 \frac{R_{ex}}{Sh_x}}.
\]
(17)
Where, $C_f$, $\tau_w$, $q_w$ and $q_m$ are Skin-friction coefficient, Shear stress, plate heat flux and plate mass flux.

3. Results and Discussion
In this problem we studied the motion of non-Newtonian nanofluid with heat and mass transfer over a semi-infinite vertical flat plate stressed by a uniform external magnetic field. The problem is formulated mathematically by a system of nonlinear partial differential equations (3)-(7). Using suitable similarity variable the governing equations (3)-(7) are transformed into a system of non-linear ordinary differential equations (11)-(14). The Mathematica ParametricNDSolve package is employed to solve the obtained system (11)-(14) numerically.

Using the default values of the physical parameters $P_r=1, R_{ex}=2, N_r=0.1, N_h=0.5, L_v=2, \varepsilon=1, \delta=0.5, G_r=0.5, G_{c_e}=0.5, \gamma=0.5, \lambda=0.2, M=0.5, K=0.5, E_c=2$, the velocity, temperature and concentration distributions as well as skin fraction and rate of the heat and mass transfer are discussed and illustrated graphically through set of figures (2-7):

![Graphs of velocity, temperature, and concentration distributions](image)

**Figure (2):** Study the variation of the velocity distribution, temperatures and concentration against the Grashof number $Gr$.

**Figure (2):** Shows the relation between the velocity $f'(\eta)$, the temperature $\theta(\eta)$ and the concentration $\phi(\eta)$ with respect to the Grashof number $Gr$. It is observed that the Grashof number signifies the relative effect of the buoyancy force to the hydrodynamic viscous force in the boundary layer. The positive values of $Gr$ correspond to cooling of the plate and the negative values of $Gr$ correspond to heating of the plate by free convection. As expected, it is found that the increase in the Grashof
number leads to increase the velocity, decrease the concentration and troubled increase in temperature due to enhancement in the buoyancy force.

Figure (3): Study the variation of the velocity distribution, temperatures and concentration against the Magnetic field M.

Figure (3) Illustrate the magnetic field effects on velocity, temperature and concentration. The Lorentz force introduced by the magnetic field normal to the fluid motion decreases fluid velocity. This type of resisting force reduces fluid velocity, increase temperature and decrease concentration.

Figure (4): Study the variation of the velocity distribution, temperatures and concentration against the permeability parameter k.
Figure (4) represents the influence of permeability parameter $K$ on velocity, temperature and concentration. Increasing the permeability parameter $K$ increases velocity and temperature while decreases concentration. The porous media creates huge resistance to fluid flow and consequently minor changes occur in momentum boundary layer.

Figure (5): Study the variation of the velocity distribution, temperatures and concentration against the Brownian motion parameter $N_b$.

Figure (5) illustrate the result of effects of Brownian motion parameter $N_b$ on velocity, temperature and concentration. The study shows that the increase in the Brownian motion parameter $N_b$ increases velocity, temperature and decrease fluid concentration. This is due to the Brownian motion parameter is a random movement of microscopic particles suspended in liquids or gases resulting from the impact of molecules of the fluid surrounding the particles.
Figure (6): Study the variation of the velocity distribution, temperatures and concentration against the Chemical reaction parameter $\gamma$.

**Figure (6)** Study the relation between velocity, temperature and concentration for different values of the chemical reaction parameter $\gamma$. Based in this study the increase in chemical reaction $\gamma$ increases the velocity, temperature and concentration decreases as a result of the converted chemical force into energy.

Figure (7): Study the variation of the velocity distribution, temperatures and concentration against the Eckert number ($E_c$).

**Figure (7)** shows the effect of Eckert number $E_c$ on velocity, temperature and concentration.
The positive values of Eckert number indicates plate cooling, that is, loss of heat from the surface to the fluid so that the greater values of viscous dissipative heat cause enhancement of temperature and velocity profile as well. In addition, the magnitude of the thermal boundary layer became large because of viscous dissipation effect. This leads to the increase in velocity and temperature but decreasing concentration.

**Conclusion:**

Based on the above study we conclude the following results:

- The effects of some physical quantities (Eckert number $E_c$, Prandtl number $P_r$, Lewis number $L_e$, Reynolds number $R_e$, Chemical reaction parameter $\gamma$, Brownian motion Parameter $N_b$, Thermophoretic parameter $N_t$ and the fluid material parameter $E, \delta$) it has significant effects on both the velocity, temperature and concentration.
- The Grashof number signifies the relative effect of the buoyancy force to the hydrodynamic viscous force in the boundary layer.
- Any increase in the Grashof number increases the velocity but decrease concentration and make trouble increase in the temperature due to the enhancement in the buoyancy force.
- Increasing the permeability parameter $K$ increases the velocity profile throughout the boundary layer.
- The presence of porous media creates huge resistance to fluid flow due to which trifling changes occurs in momentum boundary layer and hence inciting of fluid temperature and decreasing in concentration appeared.
- Increase Eckert number increase fluid temperature and velocity.

**Applications:**

The most interesting applications of the considered problem are in petroleum industries, human blood flow, heat and mass transfer and rheology, as following:

• The demand of a better drilling fluid increases when oil and gas companies turn their attention to new search areas such as the unstable shale areas and high pressure. Nanotechnology can improve viscosity, density, specific gravity and any other physical properties of the drilling fluid to overcome any difficulties.

• Human blood can be treated as a kind of a considered fluid due to the presence of several substances like, protein, fibrinogen and globulin in aqueous base plasma.

• The importance of rheology science comes from its industrial applications where synthetic polymers and their solutions in different solvents is necessary for polymers and industrial application.

• A wide variety of industrial processes involve the transfer of heat energy. Throughout any industrial facility, heat must be added, removed, or moved from one process stream to another and it has
become a major task for industrial necessity. These processes provide a source for energy recovery and process fluid heating/cooling.
