To continue the scientific path specialized in enhancing the thermal performance of thermal systems, several tests are carried out to improve the overall performance of a rectangular duct as air-flows through it. This study reports experimentally and numerically the heat transfer enhancement and overall performance of a rectangular air duct with various arrangement of continuous and intermittent ribs turbulators. The ribs are inserting in several array arrangements at a 90° relative to the direction of flow. Three ribs lengths s = 30 mm, 60 mm, and 150 mm employed with the several arrangements that's tested in the current study, with the pitch ratios (p/e) = 5.0 and height ratios (e/H) = 0.330. These cases include: continuous ribs case, intermittent-continuous-intermittent ribs case, and intermittent-ribs. Reynolds number, is ranging from 10000 to 35000. The experimental work was performed by designed and fabricated test rig while the numerical work was performed in commercially ANSYS Fluent 17.2. the outcomes show that intermittent-ribs case offers the best overall performance for all tested velocities, its 1.54 for experimental study and 1.57 for numerical study at Re = 10000. Also, the highest friction factor values are found in intermittent-ribs case, it is found to be 0.082 in Re = 10000.

Key words: overall performance, intermittent ribs, continuous ribs, friction factor

### Introduction

A variety of cooling techniques have been developed recently to guarantee the maximum levels of internal heat transmission in numerous thermal applications. Enhancing heat transfer through engineering research is important and beneficial since it increases the efficiency of heating systems like heat exchangers. Considerable economic and technical savings are possible with the appropriate heat transfer technique. The design of thermal applications requires high thermal performance methodologies, which has raised interest in developing ways to increase heat transfer coefficients [1-3]. Ribs turbulaturs have efficient impact of many thermal applications such as cooling of evaporators, spacecraft radiators, air conditioning systems, and gas turbine blades [4, 5]. Researchers conducted extensive experimental and analytical studies to improve thermal performance and confirmed that obstructions in the flow path lead to an increase in the turbulence intensity of the fluid-flow. Passive methods generally involve inserting fins, fins, baffles, depressions, wires, etc. into the flow path to increase the heat transfer rate [4, 5]. Researchers conducted extensive experimental and analytical studies to improve ther-

<sup>\*</sup>Corresponding author, e-mail: sara.rabee@utq.edu.iq

mal performance and confirmed that obstructions in the flow path lead to an increase in the turbulence intensity of the fluid-flow. Passive methods generally involve inserting fins, fins, baffles, depressions, wires, etc. into the flow path to increase the heat transfer rate [6-8]. One of the most important passive techniques for increasing heat transfer is the employing of ribs turbulators. The main effect of the presence of ribs is volume reduction and cost reduction. Periodic fins are often employed to improve the heat transfer process in various cooling channels. In general, turbulent flow in channels with continuous and regularly arranged transverse fins is often used as a simple model to study the influence of roughness on heat transfer and friction coefficient properties [9]. The presence of ribs creates a complex flow field such as separation, reattachment, and relaxation in the mainstream flow, resulting in a strong secondary flow [10-12]. Le [13] presented a study using two systems to perform heat transfer and pressure drop. One of the rigs has two channels, one with aspect ratio (1/8) and the other with aspect ratio (1/4). Reynolds number was between 3000-13000. This test shows that, square ribs produce the highest heat transfer improvement. They found that thermal performance decreased as the Reynolds number raised. The heat transfer enhancements of a square channel roughened with ribs parallel to two opposing walls were studied by Rallabandi *et al.* [14]. The p/e in the range of 5-10 was applied. The range of Reynolds number that were examined was 30000-400000. The results of the experiment demonstrated that, even with a bigger pressure drop, the heat transfer coefficient raised with raising of  $e/D_{\rm h}$  and p/e. Yang and Xue [15] conducted an investigation look into the pressure loss and thermal performance in a square channel that have blocking ribs roughened. In this study, Reynolds number between 1400-4500. There was a range of 5-15 in p/e. The experimental findings demonstrated that ribs enhanced the heat transfer. Also, Bagabir et al. [16] presented a numerical study of the turbulent heat transfer characteristics of finned square channels. Reynolds number was varies between  $10^4$  and  $4 \cdot 10^4$ . The ribs were inclined at a 45° angle, arranged in series and staggered at the top and bottom of the channel. The results showed that the heat transfer improvement in channels was generally 230%-580% greater than in the case of smooth channels. Yongsiri et al. [17] presented a numerical study testing the heat transfer in channels with separated ribs. Reynolds number varied between 4000-24000. The heat transfer and pressure drop were tested. The results show that at high values of Reynolds number, the inclined fins with  $\theta = 60^{\circ}$  and  $120^{\circ}$  achieved higher thermal performance than other angles. The p/e of 10 had the greatest heat transfer coefficient. Boga and Jayavel [18] studied the effects of heat transfer and flow field in square channels with different fin geometries (rectangular, semicircular, and triangular). Inlet Reynolds number number changed from 5000-10000. All ribs were placed in a channel with p/e = 4. The findings demonstrated that, for Reynolds number under consideration, the heated wall's Nusselt number is greatest in the channel with triangle ribs. Additionally, a CFD simulation was carried out by Farooqui [19] to calculate the heat transfer in a rectangular channel. Reynolds number was varied between 5000-24000. The outcomes showed that the presence of ribs increases heat transfer compared to smooth channels. Shukla and Dewan [20] study was carried out to improve the heat transfer in square channels provided by different types of fins. Experimental data were also made four rib arrangements were used: continuous attachment ribs, continuous separation ribs, break attachment thin ribs, and break attachment thick ribs. Reynolds number from 10000-30000 and p/e = 10 were tested the damaged rib was fixed at a 90° angle, and  $e/D_h$  was 0.15, 0.10, and 0.08125. Researchers found that the standard k- $\varepsilon$  model produced better results compared to other models studied. Jennifer et al. [21] conducted a study to increase the heat transfer coefficient. The ribs utilize the internal cooling channels of the turbine blades. The p/e was 8, it was numerically demonstrated that ribs rised the turbulence level of the flow, resulting in increased heat transfer compared to a wall without fins. Bater and Mushatet [22] presented a simulation study heat transfer in straight, convergent, and divergent channels using square ribs at the top and bottom of the channel. Reynolds number range from  $7 \cdot 10^4$  to  $10^5$  was investigated. They discovered that, in comparison the straight channel, the divergent channel's thermal efficiency rises by about 18%. The current research deals with the effect of the ribs on the path of air passing at a flow inside a rectangular channel where Reynolds number ranges from 10000-35000 tests is conducted to exam channel with presence of ribs in several arrangements with p/e = 5.0 and e/H = 0.3.

### **Experimental set-up**

The testing rig is designed and constructed to fulfill the requirements of the research endeavor. It consists of the parts displayed in figs. 1 and 2, which represent the schematic design and picture of the test rig, respectively. The rectangular channel was built from a piece of galvanized iron that measured 2 mm in thickness. The dimensions of the channel are length (L = 100 cm), width (W = 15 cm), and height (H = 6 cm). Installing rib in the channel can improve heat transfer between the heated surface and the electrified fluid, which will improve performance. Seven rows of ribs are arranged in a straight line perpendicular to the direction of air-flow. Examine values of p/e = 5 and e/H = 0.33. Three rib length, *s*, of 30 mm, 60 mm, and 150 mm are tested in different configurations. As in fig. 3.

Figure 1. The photograph view of the test rig

Figure 2. The schematic diagram of test rig

Figure 3. The configurations of the ribs cases; (a) CR case, s = 150 mm, (b) ICIR case, s = 150, 60 mm, and (c) IR case, s = 60 mm and 30 mm

### Numerical analysis

The geometry consists of a 3-D rectangular channel with ribs turbulator arranged in parallel one by one. In this section, three cases for ribs arrangements array are considered. The first case is continuous rectangular ribs on the lower surface of the channel (CR), the second is intermittent-continuous-intermittent ribs (ICIR), and the third is intermittent-ribs (IR). The numerical analysis carried out utilizing ANSYS FLUENT 17.2 software to simulate 3-D turbulent air-flow and heat transfer characteristics in the roughed channel.

### Mesh construction

To achieve discretization in space, the flow field must be divided into smaller control volumes. Control volumes of many shapes, including hexahedral and tetrahedral control volumes, can be created, as well as structured or unstructured grids. The tetrahedral mesh is utilized as shown in fig. 4 because it is effective for the separation flow. It is clear that the

mesh is incredibly small around the walls and around the ribs in order to capture the flow behavior in these regions.

### Grid independency

The geometry must be divided into cells that contain a mesh in order to model the fluid-flow problem using CFD. Choosing the ideal grid size is crucial to getting precise results. In order to determine the proper grid size for running numerical simulations over a variety of Reynolds number, tests of grid independence were conducted. Nusselt number and friction factor, f, were ascertained by performing the grid independence test at Re = 20000. Table 1 provides a summary of the findings and displays the designated grid for each form and arrangement.

The case	Number of elements	Nusselt number	Nu <sub>deviation</sub>	f	f deviation
CR: $p/e = 5$ , e/H = 0.33, s = 150 mm	2210733	92.0123	0.0142	0.0563	0.014
	2344658	90,684	0.0126	0.0571	0.0086
	2412236	89.559	0.0085	0.0576	0.0068
	2549349	88,782		0.058	
ICIR: $p/e = 5$ , e/H = 0.33, s = 150, 60  mm	2465253	91.66	0.1207	0.068	0.037
	2486390	92.78	0.0059	0.071	0.035
	2524667	93.34	0.0051	0.074	0.011
	2579547	93.82		0.075	
IR: $p/e = 5$ , e/H = 0.33, s = 60  mm and 30 mm	2577377	100.832	0.0213	0.08	0.036
	2627738	103.204	0.01	0.083	0.024

	2810848	102.88		0.082	

Table 1. Different grids and their Nusselt and *f* for different studied cases at Re = 20000

### Governing equations

The Navier-Stokes, the energy, and the continuity equations are used to analyze turbulent flow:

Equation of continuity [23]:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \tag{1}$$

where x, y, z the are components of conservation of momentum [23]:

$$u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} + w\frac{\partial u}{\partial z} = -\frac{1}{\rho}\frac{\partial P}{\partial x} + \frac{\mu}{\rho}\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right)$$
(2)

$$u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} + w\frac{\partial u}{\partial z} = -\frac{1}{\rho}\frac{\partial P}{\partial y} + \frac{\mu}{\rho}\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 v}{\partial y^2}\right)$$
(3)

$$u\frac{\partial w}{\partial x} + v\frac{\partial w}{\partial y} + w\frac{\partial w}{\partial z} = -\frac{1}{\rho}\frac{\partial P}{\partial z} + \frac{\mu}{\rho} \left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + \frac{\partial^2 w}{\partial z^2}\right)$$
(4)

Energy equation [23]:

$$u\frac{\partial T}{\partial x} + v\frac{\partial T}{\partial y} = \alpha \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right)$$
(5)

Air was used as the working fluid. The next portion present the necessary equations to calculate the variables.

The net heat input to the fluid was specified from the electrical energy input to the system:  $Q = V \times I$  (6)

The mean heat transfer coefficient is calculated [24]:

$$\overline{h} = \frac{Q}{A_s \left(T_w - T_b\right)} \tag{7}$$

The mean wall temperature is attained [25] wall temperature at the channel's bottom surface is  $T_{w_n}$ :

$$T_{\rm w} = \frac{1}{n} \sum T_{\rm w_n} \tag{8}$$

The procedures lead to the mean bulk temperature,  $T_b$ , [26]:

$$T_{\rm b} = \frac{\int \int \int \int \rho c_p u T dx dy dz}{\int \int \int \int \rho u dx dy dz}$$
(9)

The mean Nusselt number is estimated [27]:

$$Nu_{avg} = \frac{hD_{h}}{k}$$
(10)

where  $D_h = 4A_c/C$ ,  $A_c = WH$ , C = 2(W + H), where  $A_c$  is the cross-section area of the channel and C is the circumference.

The average friction factor can be obtained by the expression [28]:

$$f = \frac{\Delta P}{\frac{1}{2}\rho u_{\text{avg}}^2} \frac{D_{\text{h}}}{L}$$
(11)

The entire performance, or thermal-hydrodynamic performance, is computed [29]:

$$\eta = \frac{\frac{|\mathbf{N}\mathbf{u}_{w}|}{|\mathbf{N}\mathbf{u}_{0}|^{1/3}}}{\left(\frac{f_{w}}{f_{0}}\right)^{1/3}}$$
(12)

#### The standard k-ε model

One of the models that is most frequently used is the standard k- $\varepsilon$  model. Two equations comprise this semi-empirical model: one for the transit of turbulent kinetic energy, k, and another for the dissipation of turbulent kinetic energy,  $\varepsilon$ . The model's derivation is predicated on the turbulence of the flow and the minimal effects of molecular viscosity. Consequently, the conventional model can only be applied to turbulent flows.

For turbulent kinetic energy, *k*:

$$\rho \left[ \frac{\partial}{\partial x} (ku) + \frac{\partial}{\partial y} (kv) + \frac{\partial}{\partial z} (kw) \right] = \frac{\partial}{\partial x} \left( \frac{\mu_t}{\sigma_k} \frac{\partial k}{\partial x} \right) + \frac{\partial}{\partial y} \left( \frac{\mu_t}{\sigma_k} \frac{\partial k}{\partial y} \right) + \frac{\partial}{\partial z} \left( \frac{\mu_t}{\sigma_k} \frac{\partial k}{\partial z} \right) + G - \rho \varepsilon$$
(13)

For energy dissipation rate,  $\varepsilon$ , [30]:

$$\rho \left[ \frac{\partial}{\partial x} (\varepsilon u) + \frac{\partial}{\partial y} (\varepsilon v) + \frac{\partial}{\partial z} (\varepsilon w) \right] = \frac{\partial}{\partial x} \left( \frac{\mu_t}{\sigma_{\varepsilon}} \frac{\partial \varepsilon}{\partial x} \right) + \frac{\partial}{\partial y} \left( \frac{\mu_t}{\sigma_{\varepsilon}} \frac{\partial \varepsilon}{\partial y} \right) + \frac{\partial}{\partial z} \left( \frac{\mu_t}{\sigma_{\varepsilon}} \frac{\partial \varepsilon}{\partial z} \right) + \rho \frac{\varepsilon}{k} G - C_{1\varepsilon} \rho \frac{\varepsilon}{k}$$
(14)

Where G is referred to the generation term and is given [30]:

$$G = \mu_t \left[ 2 \left( \frac{\partial u}{\partial x} \right)^2 + 2 \left( \frac{\partial v}{\partial y} \right)^2 + 2 \left( \frac{\partial w}{\partial z} \right)^2 + \left( \frac{\partial v}{\partial y} \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial z} \frac{\partial w}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial z} \frac{\partial w}{\partial y} \right)^2 \right]$$
(15)

### Boundary condition

A PDE requires a few more conditions to be satisfied in order to find a suitable solution and get the desired outcomes. At the inlet: w = v = 0. At pipe wall P = 0. At outlet u = v = w = 0. Smooth exit for dependent variable  $(\partial u/\partial x = \partial v/\partial y = \partial w/\partial z = 0)$  are assumed.

### **Results and discussions**

### The experimental research

Three cases with the presence of rib turbulators are introduced, CR, ICIR, and IR. Pitch to rib height ratio p/e = 5 and e/H = 0.33. As in fig. 5, CR case, the IR case and the ICIR case are compared. The values of the highest Nusselt numbers are based at IR, where the average Nusselt number values for the IR case increased by 13% when compared to the CR case, 7% when compared to the ICIR case, and 27% when compared to the smooth channel. This rise can be attributed to the fact that two recirculating regions at the intermittent first rib are distort-

ed by a recirculating part of the flow. This complex flow is passing at the second continuous rib and the forming one recirculating region. This region combines with the main flow and then the process reached intermittent third rib. The process is repeated for the other downstream ribs. As a result, there are more re-circulating zones and mixing with the hot surface, which enhances heat transfer. The rise in heat transfer in the presence of ribs is responsible for the increase in the Nusselt number because, in each case, the ribs contributed more to the fluid's recycling and mixing than the smooth channel did. This improvement in heat transfer also led to an increase in the rate of heat transfer because the obstacles created a recycling area and increased fluid turbulence. The behavior is the same in all cases – an rise in the value of Nusselt number with increased flow velocity – but the values vary because each arrangement can produce greater vortices and remixing in a different way than the others.

The IR case has the greatest values of friction factor as a comparison with the other cases and that for all the considered Reynolds number values. This is because of the change in the shape of the blockages *vs.* the flowing stream and consequently increases the surface resistance and as expected due to the suppression of the viscous sub-layer. This leads to the pressures drop rise, thus increasing the *f*-values. Figure 6 displays the differences. The aforementioned case gives the highest friction as a result of the increase in the fluid mixing rate and the formation of the largest vortices among the other cases that were compared with it, and this resulting disturbance caused a greater drop in pressure in this case, which caused this drop to increase in of friction factor according to the equation of the friction factor, in the three cases' outcomes.

In fig. 7 it has been observed that when Reynolds number rises  $\eta$  falls. When compared to the other cases, the arrangement of IR scenario yields the highest values of overall performance. The outcomes showed that there was a 12% rise in overall performance for IR case when compared to CR and a 9% increase when compared to the ICIR. The reason of rising  $\eta$  for this case is due to the enhancement of the heat transfer due to the arrangement method that allowed the difference in the size and location of the vortices formed that led to rise heat transfer.

Figure 7. The variation of the overall performance for IR, CR, and ICIR cases

In fact, the performance gradually decreases as Reynolds number rises, *i.e.* the flow velocity rise. This was happened in all cases. the enhancement in heat transfer as Reynolds number increasing is slower, because that the flow has not the sufficient time to interchange the heat transfer with rib turbulators and consequently the enhancement in the overall performance decrease.

### The comparison between the experimental and numerical studies

Figure 8 compares Nusselt number experimental and numerical outcomes gained for the case of the channel that fitted with CR ribs. The both results have average deviations of 7%. Figure 11 displays the agreements between the results for f, with average deviations of 12%. Regarding the situation of ICIR, average variations of 6% are obtained by comparing the numerical and experimental results of Nusselt number, as shown in fig. 9. In contrast, f, as in fig. 12, have average variations of 7%. Figure 10 compares the Nusselt number results for IR. There was an agreement between the results with average deviation does not exceed 6%. With regard to the f, fig. 13 an average deviation of 8%.

#### Empirical correlations

For every scenario in this work, empirical correlations between f and Nu<sub>ave</sub> have been performed using the experimental data that was gathered. The form of this analysis is obtained by using the XLSTAT software. In the case of continuous ribs, the first correlation is for varying pitch ratios and rib turbulators' heights. The empirical equations are shown in eqs. (16) and (17).

For the ribs rows in odd position  $C_1 = A_{r1}/A_c$ , for the ribs rows in the even position  $C_2 = A_{r2}/A_c$ , where  $A_c = WH$ ,  $A_{r1} = s \cdot e$  (for the ribs rows in the odd position),  $A_{r2} = s \cdot e$  (for the ribs rows in the even position), where  $A_{r1}$  is obstruction area of ribs row in the odd position,  $A_{r2}$  is obstruction area of ribs row in the even position. For  $10000 \le \text{Re} \le 35000$ :

$$Nu = 1.23562(C_1)^{0.04597}(C_2)^{-0.243} Pr^{0.4} Re^{0.46093}$$
(16)

$$f = 9.633354(C_1)^{-0.21862}(C_2)^{-0.56202} \operatorname{Pr}^{0.4} \operatorname{Re}^{-0.40867}$$
(17)

For the Nusselt number and *f*, the differences between empirical correlations and experimental values are within 3% and 2%, with Reynolds number values under consideration, as in figs. 14 and 15, where p/e = 5 and e/H = 0.3.

The second case is ICIR case, whereas correlation eqs. (18) and (19) are calculating depending upon the obstruction ratios made by the rib turbulators, which represent the ratio between the areas of obstruction the surface area of the channel for  $10000 \le \text{Re} \le 35000$ :

$$Nu = 1.1412C_1^{-0.448}C_2^{0.09392}Pr^{0.4}Re^{0.40727}$$
(18)

$$f = 0.13763C_1^{-1.7702}C_2^{0.54742} \operatorname{Pr}^{0.4} \operatorname{Re}^{-0.2267}$$
(19)

For the Nusselt number and friction factor the highest variances between the predicted and experimental results are within 3% and 2%. These differences are explained in figs. 16 and 17 by using the ICIR.

Figure 16. The experimental results and empirical correlations of Nusselt number for ICIR

Figure 17. The experimental results and empirical correlations of *f* for ICIR

In the third case of IR, the rib provide obstruction ratios that are used in correlation equation calculations. where, stands for the ratio of the obstruction's area to the channel's surface area. Equations (20) and (21) show an empirical correlation of Nusselt number and f. For  $10000 \le \text{Re} \le 35000$ :

$$Nu = 3.0597 C_3^{-0.2085} C_4^{0.4432} Pr^{0.4} Re^{0.3557}$$
(20)

$$f = 1.139 C_3^{-0.222} C_4^{0.64442} Pr^{0.4} Re^{-0.273}$$
(21)

For Nusselt number and f the highest differences between the expected and actual values are within 3% and 2%. These discrepancies are illustrated in figs. 18 and 19 employing the IR example for the Reynolds number under consideration.

O Empirical correlations

Figure 18. The experimental results and empirical correlations of Nusselt number for IR

Figure 19. The experimental results and empirical correlations of *f* for IR

Figure 20. Velocity vector for the smooth channel for Re = 20000

(d)

(b)

Figure 21. Velocity vector for the CR ribs case for Re = 20000

The velocity vectors of smooth duct and with ribs present are illustrated in figs. 20-22. There are re-circulation zones following every obstacle. The core's high velocity is caused by the reduction of the core stream space at this region. The fluid's separation at the ribs' surface when it passes through them creates incredibly intricate vortices, particularly at IR.

Figure 22. Velocity vector for IR case for Re = 20000; (a) 130 mm, (b) 330 mm, (c) 550 mm, and (d) 800 mm

(a)

(c)

For air-flowing with Re = 20000, the presented results through the figures were for cross-sections at axial locations, 130 mm, 330 mm, 550 mm, and 800 mm, frames figs. 22(a)-22(d).

Figures 23-25 show the curve of temperature. The lack of circulation flow causes the fluid temperature to gradually drop from the lower to the higher portion of the channel wall. The fluid's temperature will rise as it moves downstream from the first position of 120 mm to the positions of 320 mm, 520 mm, and 720 mm. This will cause the fluid to draw more heat from the channel wall and cause the thermal boundary-layer to grow, which will cause the colder area at the upper of the channel to get smaller and smaller.

The channel's temperature distribution will be disturbed by the addition of rib turbulators. Just as the vortex flow prevents the hydrodynamic boundary-layer from growing uniformly, it will also prevent the thermal boundary-layer from developing uniformly.

### Conclusions

The impact of three different arrangement was studied for turbulent flow of air through a channel. The conclusions are as follows.

- In general, the outcomes indicate that the Nusselt number with velocity in all cases tested, and it was clear in the case of IR. This is due to the raised in mixing of the air, which provided a greater opportunity for heat exchange due to the formation of larger vortices and a rising in the re-circulation area. The maximum Nusselt number for case IR was discovered at Re = 35000.
- As the Reynolds number raises from 10000-35000, the channel's overall performance at the three cases is decreasing. Furthermore, the outcomes indicates that case IR give the maximum overall performance at Re = 5000, its 1.54 for experimental study and 1.57 for numerical study.

*L* – length of channel, [m] Nu – Nusselt number, [–]

Re – Reynolds number, [–]

p – pitch of ribs, [m]

s – length of ribs, [m] T – temperature, [K] W – width of channel

- Compared to CR, the friction factor rises while employing the ICIR for all Reynolds values and it's have the greater values at IR case.
- At Re = 10000 and Re = 35000, the highest friction factor for using the IR configuration is found to be 0.082 and 0.063, respectively.
- As the Reynolds number rise from 10000-35000, the channel's overall performance at the ICIR decreases from 150-98%.
- The results of the numerical work in general showed slightly higher values than the theoretical results due to the standard conditions in which the numerical work is carried out compared to laboratory experiments.
